Abstract

Did the summer 2016 release of Nintendo's popular franchise cause players in the US to "Pokémon Go to the polls?" Using geolocated voter file data on individual-level turnout in combination with locations of reported legendary Pokémon sightings, we develop an instrumental variables strategy to estimate the effect of increased Pokémon Go play on voter turnout. We find that a two-hour increase in daily hours logged the week before Election Day caused an 8 percentage-point increase in 18-35 year-old turnout. To explore the underlying mechanisms, we note that our effect is concentrated entirely among potential voters from states with same-day registration policies who resided near polling places that were also next to shiny Pokémon release events on Election Day. We conclude that our effect is most likely caused by players walking outside to catch Pokémon and accidentally walking up to a voting booth.

Introduction: What Are the Main Determinants of Voter Turnout?

It is well-known within political science that the impending release of Pokémon Gold and Silver cost Al Gore the White House. However, political scientists in recent years have failed to study this critical source of political mobilization.
